### Enhancing the Accuracy in Identifying Rice Species Using Support Vector Machine in Comparison With Gradient Boosting Machine

#### INTRODUCTION

- > The remarkable capacity of Support Vector Machines (SVMs) to capture complicated feature linkages and set exact decision boundaries makes them very valuable in the field of rice species identification. Because of this, SVMs can recognize subtle differences across species with accuracy.
- > SVMs have a strong emphasis on maximizing the margins between classes, which is a tactical method that aids in improving and classifying rice species with sharper distinctions. as well as the model's strong generalization to new data. Conversely, gradient boosting algorithms usually produce borders that lack subtlety.
- Furthermore, SVMs show a notable ability to effectively handle overfitting issues that are commonly observed in highdimensional datasets related to tasks involving the identification of rice species, ensuring consistent and robust performance even in complex data environments.

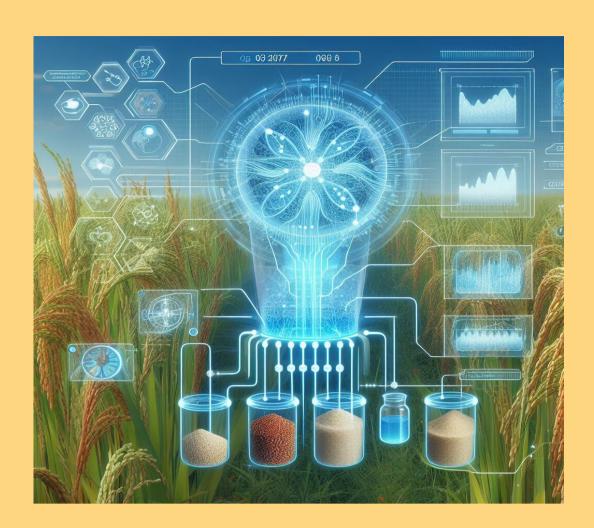

Fig 1 Rice species identification

### **MATERIALS AND METHODS**

#### **Data Collection**

Describe the source of the dataset containing images or features of rice species. Detail the characteristics of the dataset, including the number of samples, classes, and any preprocessing steps applied.

#### **Data Preprocessing**

- Clean, transform, and scale data.

RESULTS

#### Support vector machine(SVM)model

- Identify relevant features to distinguish rice species.
- Optimize SVM parameters like kernel type and regularization.
- Scale features to ensure SVM's robust performance.

**Gradient boosting machine** 

GBM algorithms are less sensitive to

feature scaling but may benefit from

categorical feature encoding.

Ensure that categorical variables are

appropriately encoded before training

the GBM model.

#### **Model EvaluationDefine the**

evaluation metrics used to assess the performance of the models, such as accuracy, precision, recall, F1-score, and area under the receiver operating characteristic curve Justify the choice of evaluation metrics based on the problem

context.

- **Model Integration** Train SVM and GBM models.
- **Compare performance** metrics.
- Analyze feature importance.
- **Address computational** resources and ethical considerations.

- Handle class imbalance.
- Split data and implement cross-validation.

Table 2. Mean, Standard Deviation and Standard error mean with accuracy rate comparison of Support vector machine over **Gradient boosting machine algorithm** 

**Model Comparison** 

Present the results of experiments comparing the

performance of SVM and GBM models.

Include tables or graphs illustrating classification

accuracy and other evaluation metrics.

|          | Group            | N  | Mean  | Std.<br>Deviation | Std. Mean |
|----------|------------------|----|-------|-------------------|-----------|
| Accuracy | SVM<br>Algorithm | 10 | .9020 | .04662            | .01474    |
| <b>A</b> | GBM<br>algorithm | 10 | .8370 | .05417            | .01713    |

#### **DISCUSSION AND CONCLUSION**

- > Accuracy for rice species identification: 0.93, with precision and recall for "Cammeo" at 0.92 and 0.93 respectively, and for "Osmancik" at 0.94 and 0.93 respectively, supported by 762 samples.
- > Noisy GBM model achieved an accuracy of 0.84, with precision-recall pairs for "Cammeo" at 0.85-0.78 and for "Osmancik" at 0.83-0.89, supported by 762 samples.
- Future scope involves exploring deep learning and integrating spectral imaging for enhanced accuracy in rice species identification, considering factors like data quality, environmental variability, and limitations in real-world adaptability and computational scalability.
- > The robust classification performance, marked by high accuracy and precision metrics, highlights the model's effectiveness in rice species identification, vital for agricultural decisions and biodiversity preservation.
